DNA sequencing is the process of determining the order of nucleotides in DNA. It includes any method or technology that is used to determine the order of the four bases: adenine, guanine, cytosine, and thymine. The advent of rapid DNA sequencing methods has greatly accelerated biological and medical research and discovery.

With rapid advances in understanding molecular pathogenesis of human diseases in the era of genome sciences and systems biology, it is anticipated that increasing numbers of therapeutic genes or targets will become available for targeted therapies.

The Foundation Fighting Blindness's scientists, donors and volunteers made 2015 an outstanding year in our fight against blindness. As I tabulated the year's top 10 research advances—all made possible through FFB funding—I realized that eight are for clinical trials of emerging therapies that are launching or underway.

Gene body methylation reduces spurious transcription and transcriptional noise. We performed WGBS on DNA extracted from three replicate nubbins per tank and obtained data from 98% of all CpGs in the genome with a per-sample, per-position mean coverage of ~25Å— (discussion S1 and data S1).

Targeted genome editing using artificial nucleases has the potential to accelerate basic research as well as plant breeding by providing the means to modify genomes rapidly in a precise and predictable manner.

Near the iap gene lay five identical segments of DNA. DNA is made up of building blocks called bases, and the five segments were each composed of the same 29 bases. These repeat sequences were separated from each other by 32-base blocks of DNA, called spacers.
